1. INTRODUCTION

1.1 Purpose and Objective

This Technical Memorandum (TM) presents the methodology and results of the soil background metals sampling and analysis methodologies used in the Airport/Klondike Area (the Site) of the Pratt & Whitney (P&W) facility located at 400 Main Street (Main Street facility) in the Town of East Hartford, Connecticut. Background soil metals data were collected from undisturbed areas of the North Klondike, as part of the remediation of the X-194 Test Stand in the North Klondike Area, to characterize the nature and distribution of natural metals in the unconsolidated materials at the Site. Additionally, background soil metals data for glaciolacustrine sediment samples were obtained from soil borings selected from portions of the Airport/Klondike Area where contamination was not identified in the overlying soils.

1.2 Background

The Airport/Klondike Area is located on the eastern portion of the P&W Main Street facility on the east side of the main plant, north of Brewer Street and south of Silver Lane. The Airport/Klondike Area consists of four study areas that include the North and South Airport Areas and the North and South Klondike Areas. Previous investigations at the Site performed from 1990 through 1997, as area-specific investigations and site-wide investigations related to environmental conditions, have resulted in the installation of numerous soil borings, monitoring wells, and surficial soil samples throughout the Airport/Klondike Area.

During the remediation activities associated with the X-194 Test Stand in the North Klondike, soil samples were collected in portions of the North Klondike from reportedly undisturbed areas and areas that have been disturbed, but never used for industrial activities. The X-194 Test Stand was used for the testing of beryllium-based fuels. Therefore, as part of establishing target clean-up levels for the remediation activities, the background concentration of beryllium had to be determined. Analyses for background concentrations in soil were conducted for all of the metals listed in Title 40 of the Code of Federal Regulations, Part 261, Appendix IX (40 CFR 261 Appendix IX). The Appendix IX metals include antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, lead, mercury, nickel, selenium, silver, thallium, tin, vanadium, and zinc, and additionally aluminum, silicon, and sodium.

As part of the most recent site investigation activities, soil borings were installed throughout the Airport/Klondike Area. Analytical data and historical operations information associated with

DRAFT

these selected soil boring locations indicated that these borings were located upgradient of potential contaminant release area. Samples from these soil borings of the underlying glaciolacustrine sediment, generally referred to as clay, were submitted for laboratory analysis of metals. Data from this site characterization has been used as sitewide background data for the current site investigation activities throughout the Airport/Klondike Area.

1.3 Scope

This TM covers the sampling and analyses of the background soil samples collected during the investigation and remediation of the X-194 Test Stand for the period 1993 through 1994, and glaciolacustrine sediment samples collected during various soil boring programs for the period from 1992 through 1997. This TM describes the soil sampling and analytical methods, the analytical results, and the statistical analysis of the data, and the development of background soils metals concentrations.

1.4 General Geologic and Hydrogeologic Conditions

The geologic and hydrogeologic characteristics of the Site are discussed in detail in the main body of this report. In general, the surficial materials in which the majority of the monitoring wells are screened, consist of medium to fine grained sands with trace levels of fine gravels and coarse sands. These sediments are generally post-glacial, fluvial deposits associated with the Connecticut River, although in many places the upper portion of these sediments have been anthropogenically disturbed during on-site construction activities. Beneath the fluvial sediments are glaciolacustrine sediments, primarily laminated silts and clays, associated with glacial Lake Hitchcock. The basal sediment layer over most of the area is glacial till and stratified drift. Bedrock in the general East Hartford area consists of Triassic Age, interbedded arkoses and basalts. Bedrock in the area has a general slight dip eastward cut by widespread steep faults.

The regional drainage basin is the Upper Connecticut River Basin. Regional flow in the unconsolidated materials in this part of the basin is to the west, towards the Connecticut River. Local groundwater flow is also controlled to some extent by local drainage sub-basins and topography. The upper portion of the unconsolidated sediments serves as the primary aquifer in the area. Groundwater flow in the bedrock is primarily within fractures and fault planes, and to a lesser extent within the rock matrix. The local bedrock aquifer would be adequate as a residential water supply source, but groundwater yields are typically too low to be of commercial or industrial use.

DRAFT

1.5 Soil Types

Soils within the Airport/Klondike Area were mapped by the US Soil Conservation Service (SCS) in the 1950s. At that time, the soils at the Site were mapped by the SCS as Made Land, Ninigret Fine Sandy Loam, Windsor Series Loamy Fine Sand, the Walpole Series Loam, the Saco Series Loam, and the Sudbury Series Fine Sandy Loam. The distribution of soil types, as mapped by the SCS (1962), is shown on Drawing TM4-1. These soil types are described by the SCS (1962) as follows.

Made Land *Made land occurs where the surface soil and subsoil have been stripped, and where earth, trash, or both, are used as fill material. It also occurs where sand and gravel have been removed and the unwanted material was left in ridges or mounds. Made land also includes areas where the soil profiles have been disturbed through leveling or other means.*

Ninigret Series The Ninigret Series consists of moderately well drained to somewhat poorly drained soils. These soils are typically coarse to medium textured and are typically developed on glaciolacustrine, glaciofluvial, and stream terrace deposits. These soils have developed from sediments derived from both crystalline rocks and the Triassic shales and sandstones.

Ninigret Series Fine Sandy Loam *(0 to 3 percent slopes) This soil has a light fine sandy loam and sandy loam surface soil and upper subsoil. It is rapidly permeable above the seasonal high water table and has a moderate moisture holding capacity. Because the texture is coarser, it dries out faster in spring than Ninigret very fine sandy loam, 0 to 3 percent slopes. Small areas of loamy fine sand are included with this soil type.*

About 25 percent of the acreage is in forest. Cleared areas are used mainly for tobacco, potatoes, hay, and pasture. Some of the acreage is used for silage corn, sweet corn, vegetables, nursery stock, and alfalfa. Without drainage, the soil generally is suited to silage corn, late vegetables, hay, and pasture. Fully drained or partly drained areas are suitable for tobacco, potatoes, and general crops. However, tobacco and potatoes are subject to damage in very wet seasons during the summer. Fertilizers are needed to produce high yields. Applied plant nutrients, however, leach out fairly rapidly. This soil requires management that will maintain the supply of organic matter and good tilth.

DRAFT

Saco Series The Saco Series consists of frequently flooded, very poorly drained soils on flood plains. These soils, which generally occur in slight depressions that border terrace escarpments or uplands, in old oxbows and narrow floodplains, generally has a dark gray to black silt loam to loamy sand surface. The subsurface of Saco Series soils is generally mottled with gray. Water may stand on the surface of these soils for long periods during the winter and spring.

Saco Silt Loam *(0 to 3 percent slopes) This soil is used mainly for forest, unimproved pasture, and wildlife because it is very poorly drained and frequently flooded. Unimproved pastures furnish some grazing in dry seasons. Drainage is generally not practical because of frequent flooding and the lack of suitable outlets.*

Sudbury Series The Sudbury Series soils consist of moderately well drained soils that have developed on sand and gravel deposits of stream terraces. These soils typically occur in small areas throughout Hartford County.

Sudbury Fine Sandy Loam *(0 to 3 percent slopes) This soil is rapidly permeable, but a seasonal high water table interferes with internal drainage. Mottles at depths of 10 to 18 inches indicate that the lower subsoil is waterlogged in wet seasons. The soil is fairly easy to drain, because it is underlain by sand and gravel. A few areas having slopes of 3 to 6 percent are included with this soil.*

About 60 percent of the acreage has been cleared and is used mainly for hay and pasture. Some acreage is used for tobacco, potatoes, vegetables, silage corn, and other crops. Undrained areas are generally suited to hay, pasture silage corn, and late vegetables. Drained areas are fairly well suited to tobacco, potatoes, and other crops. Even if the soil is drained, tobacco and potatoes are subject to damage in very wet growing seasons. The soil needs fertilizer, drainage for some crops, and management that will maintain tilth and the supply of organic matter.

Windsor Series The Windsor Series soils consist of very droughty sand and loamy soils which have typically developed on nearly level to sloping and rolling terraces. Well-defined dunes occur in areas of loamy fine sand where reworking by wind has taken place. Areas of loamy fine sand and fine sand are essentially free of gravel.

Windsor Series Loamy Fine Sand *(0 to 3 percent slopes) This soil is very rapidly permeable and has a low moisture-holding capacity. It is excessively*

DRAFT

drained and warms very early in spring. It responds to fertilizer when the moisture supply is adequate.

About 75 percent of the acreage is forested, idle, or in urban development. Tobacco and sweet corn are the main crops, but some acreage is used for early vegetables, corn, alfalfa, pasture, and other crops. Alfalfa grows fairly well. This soil is not well suited to crops, hay, and pasture because of droughtiness. A large part of the tobacco, sweet corn, and early vegetables is irrigated. If fertilizer is applied in large quantities, good yields of crops are obtained.

Walpole Series Walpole Series soils consist of moderately coarse to medium texture, poorly drained soils which have developed from sandy or sandy and gravelly stream terrace deposits. Because these soils are poorly drained they qualify as wetland soils under the Regulations of Connecticut State Agencies (RCSA).

Walpole Series Loam (0 to 3 percent slopes) *This soil includes loam, very fine sandy loam, and silt loam textures.*

Use, suitability, and management are essentially the same as for Walpole sandy loam, 0 to 3 percent slopes. (About 50 to 60 percent of the acreage is in forest, and some is idle. A large percentage of the cleared area is used for pasture and hay. Small areas are drained or partly drained and are used for silage corn, sweet corn, tobacco, potatoes, vegetables, and other crops. Undrained areas are best suited to sod crops. Partly drained areas are suited to silage corn and late vegetables. Well-drained areas are fairly well suited to tobacco and potatoes. The soil is not suited to alfalfa and tree fruits. The major needs of this soil are drainage, fertilizer, and lime. The soil is relatively easy to drain because of the sandy, gravelly substrata.) Because of the finer texture, this soil dries out somewhat more slowly in spring. If drained, it is not quite so well suited to cultivated crops.

1.6 Soil Sampling Locations and Rationale

The general distribution of surficial materials as mapped by the SCS (1962) is shown on Drawing TM4-1. The main areas of activity in the Klondike Area were done on Made Land or areas which were once Walpole Fine Sandy Loam. In addition, Ninigret Fine Sandy Loam is also present over large areas of the Klondike. It is thought that the Ninigret Fine Sandy Loam is

DRAFT

compositionally similar to the Walpole Fine Sandy Loam and therefore this soil type was not considered separately.

In addition to the soils developed on the surficial stream terrace deposits, the Airport/Klondike Area is underlain by glaciolacustrine sediments. Although these glaciolacustrine sediments are not exposed at the surface, and none of the soils on the Site have developed directly from these materials, the glaciolacustrine sediments are thought to represent a significant hydrologic boundary. Therefore, samples of the glaciolacustrine sediments were analyzed to provide information regarding the distribution of natural metals in this material.

To provide a comparison between the natural soils and the Made Land present in the North Klondike, eight sampling locations from a reportedly undisturbed area north of the X-194 Test Stand and eight sampling locations from an area of Made Land east of the test stand were chosen. The samples from the undisturbed area were located in an area of Walpole Series soils. Both of the sampling areas were reported to be located sufficiently far from the test stand to have been unaffected by site operations and activities. The X-194 Test Stand is located on an area of Made Land, reportedly created from Walpole Series soils.

Sampling locations were chosen from the Made Land east of the test stand to approximate soil conditions present at the X-194 Test Stand prior to the start of operations, but after the disturbance of the soils. The sampling locations from the Walpole Series soils were selected to approximate soil conditions at the X-194 Test Stand prior to construction. Additionally, the location of the sampling points being sufficiently far from the X-194 Test Stand to have not been influenced by test stand operations.

Samples of the glaciolacustrine sediments were collected during the installation of contaminant delineation borings. Selected samples were analyzed for metals during the course of the various investigations at the Site. Samples included in this TM were selected based on the geologic descriptions provided by the field personnel, the analyses performed on the samples, and the analytical results from overlying samples in that soil boring. In general, samples were selected from areas where metals were not considered the primary contaminants. If possible, to reduce the possibility of contamination from overlying materials, samples selected for this analysis were not the uppermost clay sample logged for the boring, but were from 0.5 to 1 foot below the upper clay boundary.

DRAFT

The locations of the sixteen soil sampling locations, NK-SB-100 through NK-SB-115, are shown on Drawing TM4-2. The locations of the glaciolacustrine sediment sampling locations are shown on Drawing TM4-3.

2. METHODOLOGY

This section presents the methods and techniques used to collect, describe, and analyze the background soil samples collected in the North Klondike Area by Fuss & O'Neill, Inc. (F&O) (F&O, 1994). In addition, this section provides a brief description of the methods used to collect samples of the glaciolacustrine sediments by Loureiro Engineering Associates, P.C. (LEA).

2.1 General Procedures

Based upon the general location requirements, background soil sampling locations were field located by F&O personnel. The sampling locations appear to have been either randomly selected in the field or selected as representative of the desired soil type based upon the judgment of the field sampling crew. The background soil sampling locations were recorded on the field sampling data sheets, along with other pertinent information. All background soil samples of Made Land and Walpole Series soils were collected on December 17, 1993. Details of the chain-of-custody, storage and handling, and laboratory submission were unavailable.

Background soil sampling was expanded to include glaciolacustrine sediments collected during investigations conducted at various environmental units in the Airport/Klondike Area. The soil borings installed during the most recent investigation activities were installed in general accordance with the procedures described in LEA Standard Operating Procedures (SOP) *Standard Operating Procedure for Geoprobe® Probing and Sampling*, the LEA SOP *Standard Operating Procedure for Geologic Logging of Unconsolidated Sedimentary Materials* and the LEA SOP *Standard Operating Procedure for Soil Sampling*.

2.2 Soil Sampling Methods

2.2.1 Walpole Series and Made Land Soil Sampling Methods

The sixteen Walpole Series and Made Land soil samples were collected by removing the vegetative cover or organic soil layer and troweling a sufficient volume of soil for the analytical procedures directly into 4-ounce, glass sample containers with Teflon®-lined lids. At the time of sample collection, field personnel recorded sample identification information, including sample number, time and date of collection, field personnel identification, and sampling location identifier, and descriptive information for each sample, including soil type, color, apparent grain size information, moisture content, and other appropriate information. This field sampling

DRAFT

information was recorded on field data sheets by F&O personnel. Copies of the field data sheets are included in Attachment A.

2.2.2 Glaciolacustrine Sediment Sampling Methods

Eighteen samples of the glaciolacustrine sediments underlying the upper unconsolidated materials of the Site have been collected from soil borings and submitted for laboratory analysis.

The soil borings selected were ones in which contamination was not identified. These samples were collected using the LEA Geoprobe® direct-push drilling system and Macro-Core® soil sampling system. These methods are more fully described in Technical Memorandum 5, *Soil Sampling*.

In brief, the Geoprobe® direct-push drilling system consisted of a truck-mounted, hydraulically operated percussive hammer device. The hammer was used to drive a sealed Macro-Core® soil sampler to an operator selected depth. At the selected depth, the seal was retracted by the operator, and the sampler was then driven to the final sampling depth which forced soil into the sampler. The sampler was lined with expendable polyethylene terephthalate copolyester (PETG) liners which were removed after the sampler was recovered from the borehole. After the sample liner was removed from the sampler, the contained soil was sampled for specific analytical and geologic requirements, as necessary.

2.3 Analytical Procedures

All sixteen of the surface soil samples were submitted to Ceimic Corporation for analysis of all 40 CFR 261 Appendix IX metals, including antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, lead, mercury, nickel, selenium, silver, thallium, tin, vanadium, zinc, and additionally for aluminum, silicon, and sodium. Laboratory reports for these surface soil samples were submitted directly to P&W and only summary analytical information was reported by F&O (F&O, 1994).

The glaciolacustrine sediment samples were analyzed by Averill Environmental Laboratory, Inc. (AEL). Samples were submitted to AEL were analyzed for arsenic, barium, cadmium, chromium, lead, mercury, nickel, selenium, silver, and zinc. Analytical data from AEL was submitted to LEA directly in both hardcopy and electronic formats and was directly incorporated into the site database maintained by LEA.

DRAFT

2.4 Decontamination of Materials and Equipment

Dedicated sampling equipment was used during the sampling of the Walpole Series and Made Land soils. Field decontamination was not required for the dedicated equipment as it was precleaned and disposed of after a single use.

Samples of the glaciolacustrine sediments were not collected as part of a separate soil sampling program, but were anecdotal samples obtained during the installation of various soil borings. The purpose of consistent decontamination procedures was to prevent the potential spread of contamination between boreholes and samples, and from the immediate work area around the well borehole. All equipment and materials placed into a borehole or associated with the collection and sampling of soil from a borehole was decontaminated prior to initiating the drilling activities and between individual samples, as appropriate. Decontamination procedures are presented in the LEA SOP *Standard Operating Procedure for Hollow Stem Auger Soil Borings*.

Downhole equipment (e.g., drill rod, Macro-Core® sampling tubes, etc.) were decontaminated prior to initiating any drilling activities at the Site. Sampling equipment such as Macro-Core® sampling tubes and stainless steel spatulas were decontaminated between uses in the field at the drilling site or the decontamination pad. The decontamination pad was typically a portable plastic or metal basin of sufficient volume to hold drilling equipment which could be laid beneath the back end of the drilling rigs to contain the spent decontamination fluids.

The sampling equipment was decontaminated using the following procedure:

- Brush off gross soil particles.
- Wash and scrub equipment with phosphate-free detergent.
- Rinse equipment with deionized water.
- Rinse equipment with dilute nitric acid solution.
- Rinse equipment in deionized water.
- Rinse equipment with dilute methanol in water solution.
- Rinse equipment in deionized water.
- Allow equipment to air dry.

The decontamination water was maintained in 5-gallon buckets during use, and transferred to 55-gallon drums for disposal. LEA field personnel were responsible for preventing cross-contamination between soil samples collected for laboratory analysis. Sample preparation tables

DRAFT

were covered with clean, disposable plastic. Clean, disposable plastic was also laid on the ground beneath the sample preparation tables and the decontamination solutions to catch dropped soil and spilt decontamination solutions.

2.5 Sample Location Identifiers

Monitoring wells, as well as piezometers, stream gauges, soil borings, surface water and sediment sampling locations have been identified using a systematic method to prevent duplication of location identifiers, and relatively easy means of finding the referenced location on site maps. All areas of the Pratt & Whitney East Hartford facility (including the Andrew Willgoos Turbine Laboratory, the Colt Street wastewater treatment facility, and other areas of the facility not included in this TM) have been assigned two-letter identifiers based upon the common name for the area. These two-letter designations are presented in Table 1.

In addition, each type of sampling location has been assigned a two-letter designation to distinguish the various type of sampling, locations possible. The two-letter designations for the various sampling locations are also presented in Table 1. Because of the large number of soil and water monitoring locations existing on site, and the large areas involved, the Airport and Klondike areas have each been broken down into northern and southern sections. All monitoring and sampling locations have been given a location identifier based on their location in the Airport or Klondike Areas, the type of sampling or monitoring location, and finally a sequential numeric identifier based upon the specific type of location.

2.6 Waste Management

All spent decontamination fluids generated during drilling activities and purge water generated during monitoring well development activities for the site characterization was placed in 55-gallon closed-top drums supplied by P&W for subsequent off-site disposal by P&W. The drums were labeled, the wells contributing to each was listed, and the information tracked to aid in waste characterization and disposal.

All soil cuttings generated during drilling activities were placed in 55-gallon open-top drums supplied by P&W for subsequent off-site disposal by P&W. The drums were labeled, the locations contributing to each was listed, and the information tracked to aid in waste characterization and disposal.

2.7 Health and Safety

Sampling was performed by F&O personnel under their corporate, site-specific health and safety plan. Loureiro Engineering Associates field crews conducted field operations in accordance with the LEA Site Health and Safety Plan. In general, soil sampling was conducted in modified Level D personal protective equipment (PPE) consisting of safety glasses, surgical or nitrile gloves, and hard hats and steel-toed shoes for the drill rig operators.

3. RESULTS AND CONCLUSIONS

3.1 Soil Types

At the time the background soil samples were collected by F&O personnel, a description of the collected soil was recorded on the field data sheets. The sixteen soil samples collected appear to fall into groups, based primarily upon the soil color and descriptions provided on the field sampling records. The eight samples collected from north of the X-194 Test Stand, NK-SB-100 through NK-SB-107, and one sample collected from east of the test stand area, NK-SB-108, were described as very dark brown (reported as a dusky yellowish brown, but noted as having a Munsell® color designation 10YR 2/2), medium to fine grained sand. Four of the samples collected from east of the test stand area, NK-SB-109 through NK-SB-112, were described as black (reported as brownish black, but noted as having a Munsell® color designation 5YR 2/1), fine to medium sand. Three of the samples collected from east of the test stand area, NK-SB-113 through NK-SB-115, were described as reddish brown (reported as a medium yellowish brown, but noted as having a Munsell® color designation 10YR 5/4), coarse to fine grained sand.

Descriptions of the sampling locations from the area north of the test stand area, NK-SB-100 through NK-SB-107, indicate that the soils in the general area may have been influenced to some degree by human activities. Identified in the descriptions are an access road, a chain-link fence, a "depression," a pile of wood chips, and the diverted unnamed stream. The presence of these entities indicates some degree of prior human activity in the area, however, they do not indicate that the soils were definitely altered. Two of the samples, NK-SB-103 and NK-SB-105, were reported to have foreign material described as "wood chips" present. All but two of the samples, NK-SB-106 and NK-SB-107, were identified as "wetland" soils on the field sampling records.

Descriptions of the sampling locations from east of the test stand area, NK-SB-108 through NK-SB-115, indicate that samples from NK-SB-109 through NK-SB-111 were collected from the top of two "ridges" in the area, sample NK-SB-112 was collected from a lowland area between the two ridges, and samples from NK-SB-108, NK-SB-113 through NK-SB-115 were collected in various other locations in the general vicinity. The soil sample collected from NK-SB-113 was identified as a "wetland" soil on the field sampling record.

SCS mapping of the soils appear have some inconsistencies. For instance, areas of the North Airport where the paved landing field exists are mapped as natural soils and should have been mapped as Made Land. Additionally, areas of the Klondike where historical operations and construction activities have occurred are also mapped as natural soils and should have been

DRAFT

mapped as Made Land. These apparent inconsistencies are due to the timing of the field mapping, the construction activities in the Airport/Klondike Area, and the aerial photography that was done for publication. The northeast corner of the Airport runway was extended, and construction activities in the Klondike were commenced after the field mapping activities, but before the aerial photography was performed.

For the initial analysis of these samples, F&O divided the samples into Walpole soils and Made Land, based upon the SCS mapping. However, based upon the field descriptions of the soils recorded at the time of sampling, F&O identified two soil samples, originally collected as Walpole Series soils north of the test stand area, as being more consistent with Made Land soils and grouped these results with the Made Land data. The report did not explicitly identify the two samples, however it appears that the samples were NK-SB-106 and NK-SB-107, because these samples were identified as "wetland" soils on the field sampling records, and it appears that the data from these samples were incorporated into the Made Land data during the statistical analyses. Consequently, F&O identified six Walpole soil data and ten Made Land soil data.

In general, these divisions appear to be adequate based upon the descriptions of the Walpole Series provided by the SCS, and the soil descriptions provided by the field sampling crews. The soil descriptions provided by the field sampling crews are not detailed soil descriptions, but are Burmister soil descriptions. No indication of visually identifiable disturbances to the soil structure, the presence or absence of soil structure, or other standard soil descriptions are provided.

3.2 Analytical Results

3.2.1 Walpole Series and Made Land Soils Analytical Results

Walpole Series and Made Land soil samples were submitted for analysis for the metals listed in 40 CFR 261 Appendix IX, including antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, lead, mercury, nickel, selenium, silver, thallium, tin, vanadium, and zinc, and additionally for aluminum, silicon, and sodium. Summary analytical results for the Walpole Series and Made Land soil samples are presented in Table 2. No antimony, silver, thallium, or tin was detected in any of the Walpole Series or Made Land soil samples collected.

3.2.2 Glaciolacustrine Sediment Analytical Results

Glaciolacustrine sediment samples were submitted for analysis of arsenic, barium, cadmium, chromium, lead, mercury, nickel, selenium, silver, and zinc. Arsenic, barium, cadmium,

DRAFT

chromium, nickel, and zinc were detected in the majority of the samples submitted for analysis. Lead was detected in only one sample, and mercury was detected in two samples. Summary analytical results for the glaciolacustrine sediment samples submitted for analysis are presented in Table 3. No selenium or silver was detected in any of the glaciolacustrine sediment samples submitted for analysis.

3.3 Statistical Analysis of Walpole Series and Made Land Soils Metals Concentrations

A statistical analysis of the metals data was performed to determine the average concentration of each of the metals detected in the soil samples and to estimate a maximum concentration of each analyzed metal likely to occur naturally in the onsite soils. The data from each soil type were analyzed separately. Data were analyzed to determine whether they followed a normal distribution, and for the presence of outliers. After a final data set and statistical distribution were decided upon, the data were analyzed to determine the various parameters of the data set necessary to describe the maximum expected concentrations of the detected metals in unaltered soil samples. It should be noted that, although it was not explicitly stated, non-detects were replaced by one half the detection limit in the statistical analyses and distribution testing (F&O, 1994).

The statistical test for normality of the data was the Kolmogorov-Smirnoff Test. Based upon the results of these tests, data sets may have been log-transformed and the distribution of the transformed data retested to determine its distribution. If the data were not adequately represented by either a normal or a log-normal distribution, non-parametric statistics were used to describe the data.

The data sets were inspected to determine if outliers appeared to exist, and suspected outliers were tested using the method described in "*Statistical Analysis of Ground-Water Monitoring Data at RCRA Facilities*" (EPA 1989). Data points were rejected if there was less than a five percent chance of that value having come from the population as sampled. Entire soil samples were not rejected if selected metals analyses data from that boring were rejected as outliers. That is, outliers were treated as if they were the result of random sampling or analytical errors independent of other sampling or analytical parameters. Although no evidence was presented to indicate a justification for treating these extreme values as true outliers, removal of these data from the set of values results in a more conservative estimate of the population mean and the estimated maximum likely concentration of each metal.

DRAFT

After a suitable distribution was determined, descriptive statistics were calculated to characterize the metals concentrations and determine the maximum expected metals concentrations for the Walpole Series and Made Land soils. The maximum expected concentration was operationally defined as the 95th percentile estimate for the population. The 95th percentile of the population is the concentration below which 95 percent of the population fall. The upper 95th percentile of a normally or log-normally distributed population was estimated from sample data using the following equation:

$$\bar{X}_{95} = \bar{x} + t_{0.05} \cdot s$$

where: \bar{X}_{95} is the 95th percentile of the population ,
 \bar{x} is the sample mean,
 $t_{0.05}$ is the Student's *t*-statistic value for a significance level of five percent, and
 s is the standard deviation of the sample.

Except for beryllium, cadmium and silver, of the six samples identified as Walpole soils, four to six of the samples contained detectable concentrations of the metals analyzed. For beryllium, cadmium, and silver, a value equal to one-half the detection was used in place of the non-detects.

The use of one-half the detection limit in place of the non-detect does not bias the estimate of the mean, but can bias the estimate of the standard deviation of a population (Gilbert, 1989). It is believed that, due to the relative values of the detection limit and the detected concentrations, the relative error associated with this method is acceptable for the uses of the data and is likely to be on the order of the associated measurement errors.

3.4 Statistical Analysis of Glaciolacustrine Sediments Metals Concentrations

The metals concentrations in the glaciolacustrine sediments were calculated in the same manner as the metals concentrations in the Walpole Series and Made Land soils. Only one glaciolacustrine sediment sample contained a detectable concentration of lead, and none contained detectable concentrations of selenium or silver. Two samples contained detectable concentrations of mercury. The remaining metal analytes, arsenic, barium, cadmium, chromium, nickel, and zinc, were detected in between twelve and seventeen of the samples.

The glaciolacustrine sediment metals data were analyzed to determine whether the data could be considered normally distributed. Following the methodology used for the analysis of metals concentrations in the background soils, non-detects were replaced by one-half the detection limit. The use of one-half the detection limit in place of the non-detect does not bias the estimate of the

DRAFT

mean, but can bias the estimate of the standard deviation of a population (Gilbert, 1989). It is believed that, due to the relative values of the detection limit and the detected concentrations, the relative error associated with this method is acceptable for the uses of the data and is likely to be on the order of the associated measurement errors.

In general, the data were not normally distributed. Logarithmic and exponential transformations were unsuccessful in producing a normally distributed data set. No samples were rejected as outliers based upon a lack of evidence for erroneous or improper data or samples.

Because of the general lack of normality, and in the interest of maintaining a consistent set of comparison, non-parametric analyses were used to calculate the maximum expected concentrations for each of the metals in the glaciolacustrine sediments. The maximum expected concentration was operationally defined as the 95th percentile estimate for the population. The 95th percentile of the population is the concentration below which 95 percent of the population fall. The upper 95th percentile of a non-parametric distribution was calculated by regressing the sample rank against concentration to determine the rank of the 95th percentile.

3.5 Average Walpole Series and Made Land Soil Metals Concentrations

The maximum expected concentrations of metals, as determined from the analyses of Walpole Fine Sandy Loam soil samples collected from the area north of the X-194 Test Stand area are presented in Table 4. Also included in Table 5 are similar concentration values from the Made Land soil samples.

It was noted in the original F&O report that, except for aluminum, the metals concentrations are higher in the Walpole soil samples than in the Made Land soils. F&O attributed this to the presumably generally higher humic and organic content, and higher water content of the Walpole soils, based on the fact that these soils are poorly drained, wetland type soils. The organic and humic content of these soils would complex with metals and bind them to the organic materials.

The background reference concentrations statistically calculated from the soils analyses were also compared to published reference concentrations of metals from *Elemental Concentrations in Soils and Surficial Materials of the Conterminous United States*, (Shacklette and Boerngen, 1984) to determine if the values were "reasonable." Data from Shacklette and Boerngen (1984) is presented in Table 7.

In general, the reference concentrations determined statistically from the background soil sampling are within the limits of observed soil metals concentrations reported in Shacklette and

DRAFT

Boerngen (1984), and most are also sufficiently close to the average observed concentrations to be considered “reasonable.” The only exception is the reference concentration of cadmium for the Walpole soils, which was calculated as 0.88 mg/kg and Shacklette and Boerngen (1984) report an observed maximum of 0.7 mg/kg. However, the reference concentration of 0.88 mg/kg was calculated based on two detects and four non-detects and the small deviation from a reported average concentration is not considered significant.

3.6 Average Glaciolacustrine Sediments Metals Concentrations

The maximum expected concentrations of metals in the glaciolacustrine sediments, as determined from the analyses of glaciolacustrine sediment samples from various areas of the Site, are presented in Table 6.

The metals concentration data were not compared to observed soil metals concentrations reported by Shacklette and Boerngen (1984), because these data do not represent the same type of materials as the glaciolacustrine sediments. In general, however, the reference concentrations determined statistically from the glaciolacustrine sediment analyses are similar to the data presented by Shacklette and Boerngen (1984). The glaciolacustrine sediments appear to have significantly higher concentrations of cadmium, mercury, and nickel than the materials analyzed by Shacklette and Boerngen (1984).

Metals concentrations in the glaciolacustrine sediments is a result of the initial metals content of the sediments, and subsequent metals adsorption on clay minerals during diagenesis. The metals adsorbed onto the clay mineral surfaces would be a function of the available metals, the type of clay minerals present, and the geochemistry of local groundwaters.

3.7 Conclusions

Sitewide background soil metals concentrations in Walpole Series soils and Made Land soils in the North Klondike were estimated based on soil samples collected from specific soil series in the area. Generally, the number of data points appears adequate for the Walpole Soils and Made Land areas. Although the number of data points is somewhat restricted, it is likely that additional sampling would be difficult and that the reference concentrations would not change significantly. In fact, it is possible, based on the previous decision to discard apparent outliers, that the reference concentrations would increase.

The calculated reference concentrations appear to be conservatively estimated and adequately distributed in the areas reported to represent undisturbed areas of the Site. The statistical analysis

DRAFT

of the data appears to be adequate, and the elimination of the extreme values from selected populations represents a conservative estimate of the population parameters. The calculated reference concentrations of metals in soils compare favorably to published values for occurring metals in natural soils in the United States.

Metals concentrations in the glaciolacustrine sediments underlying the upper unconsolidated sediments were estimated based on eighteen selected analyses. These data were analyzed statistically in a manner similar to that used for the Walpole Series and Made Land soils. In general, metals analyses for the glaciolacustrine sediments are similar to, but not directly comparable to, the metals data for the on-site background soils and "typical" surficial materials.

DRAFT

Table 7
Elemental Concentrations in Soils and Surficial Materials of the Conterminous United States
Airport/Klondike Area, Pratt & Whitney, East Hartford, Connecticut

Constituent	CAS Number	Concentrations Detected in Soil (mg/kg)	
		Average	Observed Range
Aluminum (fume or dust)	7429-90-5	66,000	700 → 100,000
Antimony	7440-36-0	0.67	<1 → 8.8
Arsenic	7440-38-2	7.2	<0.1 → 97
Barium	7440-39-3	580	10 → 5,000
Beryllium	7440-41-7	0.92	<1 → 15
Boron (water soluble)	7440-42-8	34	<20 → 3000
Cadmium	7440-43-9	0.06	0.01 → 0.7
Calcium	7440-70-2	24,000	<150 → 320,000
Cerium	7440-45-1	86	<150 → 300
Chromium	7440-47-3	54	1.0 → 2,000
Cobalt	7440-48-4	10	<3 → 70
Copper	7440-50-8	25	<1 → 700
Gallium	7440-55-3	19	<5 → 70
Iron	7439-89-6	25,000	100 → 100,000
Lanthanum	7439-91-0	41	30 → 200
Lead	7439-92-1	19	<10 → 700
Manganese	7439-96-5	560	<1 → 7,000
Mercury	7439-97-6	0.089	<0.01 → 4.6
Molybdenum	7439-98-7	----	<3 → 7.0
Nickel	7440-02-0	19	<5 → 700
Phosphorus (white or yellow)	7723-14-0	420	20 → 6,000
Potassium	7440-09-7	23000	50 → 70,000
Selenium	7782-49-2	0.39	<0.1 → 4.3
Sodium	7440-23-5	12000	<500 → 100,000
Strontium	7440-24-6	240	<5 → 3,000
Vanadium (fume or dust)	7440-62-2	76	<7 → 500
Zinc (fume or dust)	7440-66-6	60	<5 → 2,900

1. INTRODUCTION

1.1 Purpose and Objective

This Technical Memorandum (TM) presents the methodology and results of the soil boring installation and the soil sampling methodology used in the Airport/Klondike Area (Site) of the Pratt & Whitney (P&W) facility located at 400 Main Street (Main Street facility) in the Town of East Hartford, Connecticut. Soil borings were installed as part of the Site investigation activities to characterize the nature and the distribution of contaminants in the unconsolidated materials at the Site.

1.2 Background

The Airport/Klondike Area is located on the eastern portion of the P&W Main Street facility on the east side of the main plant, north of Brewer Street and south of Silver Lane. The Airport/Klondike Area consists of four study areas that include the North and South Airport Areas and the North and South Klondike Areas. Previous investigations at the Site performed from 1990 through 1993 resulted in the installation and sampling of soil borings, groundwater monitoring wells and temporary wellpoints throughout the Airport/Klondike Area. A brief description of the monitoring well installations is provided below. For a more detailed account of the monitoring well installations refer to TM 1, *Monitoring Well Installation and Development and Soil Sampling*.

The majority of historical soil borings installed at the Site were installed as part of the installation of the monitoring well network. In the North Airport Area, monitoring wells NA-MW-01 through NA-MW-04 were installed in October 1991 during the Site-Wide Environmental Monitoring Program at the Main Street facility by Haley & Aldrich, Inc. (H&A). In the North Airport Area, piezometers NA-PZ-01 through NA-PZ-12 were installed in November 1991 during the Site-Wide Environmental Monitoring Program.

In the North Klondike Area, wells NK-MW-01 through NK-MW-05 were installed in February 1990 during the Preliminary Reconnaissance Survey of the Airport/Klondike Area by Westinghouse Environmental and Geotechnical Services, Inc. (Westinghouse). Wells NK-MW-06 and NK-MW-07 were installed in October 1991 during the Site-Wide Environmental Monitoring Program. Wells NK-MW-08 through NK-MW-10 were installed in October 1992 during the Environmental Assessment of the Former PCB Storage Building by H&A. Wells NK-MW-12 through NK-MW-17 were installed in about April 1993 during the Klondike Area Site

DRAFT

Investigation by Metcalf & Eddy, Inc. (M&E).

In the South Klondike Area, wells SK-MW-01 through SK-MW-08S and SK-MW-8D were installed in February 1990 during the Preliminary Reconnaissance Survey. Wells SK-MW-09 through SK-MW-13 were installed in October 1991 during the Site-Wide Environmental Monitoring Program. Wells SK-MW-14I, SK-MW-15I, and SK-MW-16 were installed in about April 1993 during the Klondike Area Site Investigation.

In the South Airport Area, monitoring wells SA-MW-01 and SA-MW-02I were installed in February 1990 during the Preliminary Reconnaissance Survey. Wells SA-MW-03 through SA-MW-05S and SA-MW-05I were installed in October 1991 during the Site-Wide Environmental Monitoring Program. In the South Airport Area, piezometers SA-PZ-01 and SA-PZ-02 were installed in November 1991 during the Site-Wide Environmental Monitoring Program.

Background soil metals data were collected from undisturbed areas of the North Klondike, as part of the remediation of the X-194 Test Stand in the North Klondike Area, to characterize the nature and distribution of natural metals in the unconsolidated materials at the Site. There were sixteen soil sampling locations, NK-SB-100 through NK-SB-115, completed to provide a comparison between the natural soils and the Made Land present in the North Klondike. The analysis of these background soils is discussed in TM 4 *Background Soil Sampling and Analysis*.

1.3 Scope

This TM covers the installation, sampling, and rationale for the soil borings advanced in the Airport/Klondike Area. The methods and techniques discussed are those used by Loureiro Engineering Associates, P.C. (LEA) during the period from approximately 1994 through 1998. These methods and techniques have also been used, to a greater or lesser extent, by other consultants and contractors working at the Site at various times. However, this TM does not cover specific chemical analyses of soil samples collected during the soil boring installation as these data are discussed in the appropriate Unit-Specific Technical Memorandum (USTM).

1.4 General Geologic and Hydrogeologic Conditions

The geologic and hydrogeologic characteristics of the Site are discussed in detail in the main body of this report. In general, the surficial materials in which the majority of the monitoring wells are screened, consist of medium to fine grained sands with trace levels of fine gravels and coarse sands. These sediments are generally post-glacial, fluvial deposits associated with the Connecticut River, although in many places the upper portion of these sediments have been anthropogenically

DRAFT

disturbed during on-site construction activities. Beneath the fluvial sediments are glaciolacustrine sediments, primarily laminated silts and clays, associated with glacial Lake Hitchcock. The basal sediment layer over most of the area is glacial till and stratified drift. Bedrock in the general East Hartford area consists of Triassic Age, interbedded arkoses and basalts. Bedrock in the area has a general slight dip eastward cut by widespread steep faults.

The regional drainage basin is the Upper Connecticut River Basin. Regional flow in the unconsolidated materials in this part of the basin is to the west, towards the Connecticut River. Local groundwater flow is also controlled to some extent by local drainage sub-basins and topography. The upper portion of the unconsolidated sediments serves as the primary aquifer in the area. Groundwater flow in the bedrock is primarily within fractures and fault planes, and to a lesser extent within the rock matrix. The local bedrock aquifer would be adequate as a residential water supply source, but groundwater yields are typically too low to be of commercial or industrial use.

1.5 Soil Boring Locations and Rationale

Soil borings have been installed at the Site over the course of several years as parts of a variety of environmental investigations. Soil borings have been installed both as part of sitewide investigations of soil quality and during investigations of specific environmental units and areas. In many cases, these soil borings were located on the basis of historical information regarding Site operations, or on the basis of field observations made during numerous Site walkovers and visits. Historical operations have been reported in various reports, deduced from aerial photographs, engineering drawings and plans, and reported in various Pratt & Whitney internal memoranda. More details on historical operations are included in the main body of this report as well as in the USTMs.

2. METHODOLOGY

This section presents the methods and techniques used to install the soil borings at the Site. These methods were used by LEA, although some of the general procedures and methods were also used by previous consultants and contractors who installed soil borings.

2.1 General Procedures

Soil borings in the Airport/Klondike Area have been installed by conventional hollow-stem auger drilling rigs and by direct-push techniques using the LEA Geoprobe® drilling rig. Soil borings have been installed at the Site since approximately 1991. This TM describes the general procedures that were used during the installation of soil borings at the Site. Also discussed are variations and exceptions to the general methodology and the reasons why these variations and exceptions were required.

The soil borings installed during the most recent investigation activities were installed in general accordance with the procedures described in LEA Standard Operating Procedures (SOP) *Standard Operating Procedure for Geoprobe® Probing and Sampling*, the LEA SOP *Standard Operating Procedure for Geologic Logging of Unconsolidated Sedimentary Materials*, and the LEA SOP *Standard Operating Procedure for Soil Sampling*.

2.2 Drilling Methods

Two drilling methods were used to install soil borings, both historical soil borings and those installed as part of the current investigation activities, in the Airport/Klondike Areas. The methods used were hollow-stem augering and Geoprobe® direct-push techniques. Each of these methods is briefly described below.

The hollow-stem auger drilling method used continuous-flight hollow stem augers. The typical auger used had an inside diameter of 4.25 inches and a length of 5 feet. A pilot assembly, consisting of a surface-retractable plug for the lead-auger head, was used to avoid filling the augers with formation material. Continuous sampling with a split-spoon sampler was performed in advance of the augers. The split-spoon sampler consisted of a 24-inch long by 1.375-inch inside diameter steel sampling tube. The split-spoon sampler was driven through the 2-foot sampling interval with a 140-pound hammer with a 30-inch drop. After the split-spoon sampler was retrieved, the sampler was transferred to the attending geologist for sampling and logging. Drilling fluids were not required during the installation of soil borings using hollow-stem augers.

DRAFT

The direct-push techniques with the LEA Geoprobe® 5400 were used to install soil borings and both temporary and permanent monitoring wells. Direct-push techniques involved the initial installation of a soil boring to depth using Geoprobe® soil sampling techniques. Boreholes were advanced using the Geoprobe® Macro-Core® soil sampling equipment.

The Macro-Core® system consisted of a 48-inch long by 2-inch outside diameter steel sampling tube outfitted with disposable 46-inch long by 1.75-inch diameter polyethylene terephthalate copolyester (PETG) liners. The soil sampler was outfitted with a new liner and a fitted piston tip. The entire unit was driven to the top of the sampling interval with the Geoprobe® rig. The purpose of the fitted piston tip was to seal the end of the sampling tube against the introduction of formation material during advancement. The piston tip was released by the operator, the sampler was driven to the final sampling depth by a combination of percussive hammering and direct pressure, and the sampler was retrieved. After the sampler was retrieved, the soil-filled liner was removed from the sampler and transferred to the attending geologist for sampling and logging.

2.3 Soil Sampling Methods

Soil samples collected from soil borings were sampled in general accordance with the procedures described in the LEA SOP *Standard Operating Procedure for Soil Sampling*. Continuous soil sampling was performed during the advancement of all boreholes installed at the Site by LEA. Soil sampling procedures were similar for split-spoon samples and for Geoprobe® Macro-Core® samples.

Immediately after collection, the sample liners were sliced open using a dedicated holding frame and razor knife. All soil samples were examined by the attending geologist for indications of contamination, such as the presence of visible free-phase petroleum, visible staining, or the incidental presence of odors. Soil samples were collected directly into laboratory-supplied sample containers with Teflon®-lined lids for submission to an off-site laboratory for possible analysis. In addition, a soil sample was collected directly into a 40-milliliter vial with a Teflon® septum for submittal to the LEA Analytical Laboratory for analysis for target VOCs. After collection, all soil samples were field headspace screened with either a photoionization detector (PID) or flame ionization detector (FID) for the presence of volatile organic compounds (VOCs).

As soon as practical after the collection and opening of the sample liners, the soil samples were collected directly into laboratory-supplied glass sample containers with Teflon®-lined lids for submission to an off-site laboratory for analysis. Soil samples were collected from the opened liners using pre-cleaned stainless-steel spatulas. Filled sample containers were labeled using pre-printed, pre-numbered adhesive labels with the sampling date and time hand recorded by the

DRAFT

sampler. The filled sample containers were placed into iced sample coolers for the remainder of the sampling day.

In addition to each sample collected for the off-site laboratory, a sample was collected for the LEA Analytical Laboratory. A 5-gram aliquot of the soil was collected directly into a 40-milliliter vial with a Teflon® septum for analysis for target VOCs. Prior to collecting the sample, the analytical balance was tared against the weight of the vial. Soil samples were collected directly into the vials and the vials plus the soil were weighed to determine the weight of the soil sample collected. The vials were then filled to 30-milliliters volume with pre-preserved sampling water supplied by the LEA Analytical Laboratory. Filling of the vials was done by placing the vials into a wooden or plastic block, drilled to accept the vial, and sized to provide a top surface level with the 30-milliliter level of the vials. Filled sample vials were labeled using pre-printed, pre-numbered adhesive labels with the sampling date and time hand recorded by the sampler. The filled sample vials were placed into iced sample coolers for the remainder of the sampling day.

2.4 Analytical Parameters

Analytical parameters for soil samples collected from soil borings installed in the Airport/Klondike Area were selected on the basis of historical information regarding area-specific operations. Specific contaminants of concern were chosen based on the chemicals and materials known or suspected to have been used in the area and historical information gathered during previous environmental investigations.

Specific analyses performed on soil samples, and the rationale for selecting specific samples for analysis are discussed in the appropriate USTMs. The analytical parameters selected for all soil samples are presented in Table 1. Table 1 presents information regarding which soil samples were submitted for laboratory analyses and whether any of the target analytes for the analyses selected were detected.

2.5 Quality Assurance/Quality Control Procedures

Several Quality Assurance (QA) samples were collected to confirm the reliability and validity of the field data gathered during the Site investigation. Duplicate samples were used to provide a measurement of the sampling consistency and an estimate of variance and bias. Trip and equipment blanks were used to provide a measurement of cross-contamination sources, decontamination efficiency, and other potential errors that can be introduced from sources other than the sample.

DRAFT

Trip blanks were used on every sampling day, because samples were routinely analyzed for the presence of volatile organic compounds. Trip blanks were supplied by the analytical laboratory for each cooler/sampling event.

Equipment blanks submitted to off-site analytical laboratories were collected at the rate of approximately one equipment blank for every twenty soil samples submitted for analysis. Equipment blanks submitted to off-site laboratories were collected using laboratory-supplied distilled, de-ionized water using field decontaminated sampling equipment. Equipment blanks submitted to the LEA Analytical Laboratory were collected daily using the laboratory-supplied sampling water.

During the Site investigation, samples were collected for the purpose of defining the presence or absence of contamination. For this reason, the possession of samples, including QA/QC samples, was traceable from the time the samples were collected until they were analyzed. Chain-of-custody procedures were used to maintain and document sample possession from collection through analysis. The following documents identify samples and document possession:

- Sample labels
- Chain-of-custody record forms
- Field notebooks/Field Sampling Records

The field sampler was responsible for the care and custody of the samples collected until they are transferred under the chain-of-custody procedures. Samples collected for analysis at the LEA Analytical Laboratory were maintained under separate chain of custody, and in separate coolers from samples collected for submission to off-site laboratories.

2.6 Borehole Logging

After the retrieved soil was collected for laboratory analysis and field headspace screening, the attending geologist also visually described the soils using a modified Burmister Classification System. The geologic descriptions were recorded on standardized “Geologic Boring Log” forms in general accordance with the LEA SOP *Standard Operating Procedure for Geologic Logging of Unconsolidated Sedimentary Materials*.

The general data recorded for the subsurface materials encountered included the percentage of the sample recovered relative to the length of the sampled interval, the estimated primary grain size ranges according to the Burmister Classification Scheme, secondary grain size ranges, color, relative degree of water saturation, and visible sedimentary structures. In addition, the presence

DRAFT

of extraneous materials and foreign objects was also recorded, as was the presence of odors or staining. Copies of available soil boring logs are included in Attachment A to this TM.

Soil borings were typically located in specific environmental units in response to the presence of contaminants . Because of this, and the fact that monitoring wells were typically advanced to greater depths and located site-wide, the development of the geologic model for the Site was based on geologic information derived from monitoring wells logs. Geologic information derived from soil borings was used to supplement the data derived from the monitoring wells. Site geology is discussed in Section 5 of the report.

2.7 Borehole Abandonment

After completion of the sample collection, boreholes were abandoned to prevent the migration of contaminants into the aquifer through the open hole. Boreholes were abandoned by backfilling the open borehole with bentonite granules or small chips. The bentonite was poured slowly into the borehole to avoid bridging. The bentonite was hydrated to induce swelling and seal the borehole.

After backfilling the borehole, a surveyor's flag with the soil boring identifier was placed in the ground to temporarily locate the boring until a civil survey of the location could be completed. Soil boring locations were typically surveyed within two weeks of completion.

2.8 Historical Soil Borings

The majority of historical soil borings installed at the site were completed as part of the installation of the monitoring well network. The advancement and sampling of these borings is presented in TM 1, *Monitoring Well Installation and Development and Soil Sampling*. In general, the shallow borings which were completed as monitoring wells were advanced using hollow-stem auger drilling rigs and sampled using split-spoon techniques. Some of the deeper monitoring well borings were advanced using drive and wash techniques, and sampled using split-spoons. These techniques and methods are discussed in greater detail in TM 1.

2.9 Decontamination of Materials and Equipment

The purpose of consistent decontamination procedures was to prevent the potential spread of contamination between boreholes and samples and from the immediate work area around the borehole. All equipment and materials placed into a borehole, or associated with the collection and sampling of soil from a borehole, were decontaminated prior to initiating the drilling activities and between individual samples, as appropriate. Decontamination procedures are presented in the

DRAFT

LEA SOP *Standard Operating Procedure for Hollow Stem Auger Soil Borings*. Drilling rigs and downhole equipment (e.g., hollow-stem augers, bits, etc.) were decontaminated by steam-cleaning prior to initiating any drilling activities at the Site. Steam-cleaning took place at a decontamination pad. The decontamination pad was typically a portable plastic or metal basin of sufficient volume to hold augers and other drilling equipment which could be laid beneath the back end of the drilling rigs to contain the spent decontamination fluids.

Sampling equipment such as split-spoons and stainless steel spatulas were decontaminated between uses in the field at the drilling site or the decontamination pad. Manual decontamination took place at the drilling site using a portable decontamination system, consisting of small, portable trough to contain over-spray and potentially spilt decontamination fluids, and decontamination solutions in individual 5-gallon buckets, or spray containers, as appropriate. The sampling equipment was decontaminated using the following procedure:

- Brush off gross soil particles.
- Wash and scrub equipment with phosphate-free detergent.
- Rinse equipment with deionized water.
- Rinse equipment with dilute nitric acid solution.
- Rinse equipment in deionized water.
- Rinse equipment with dilute methanol/water solution.
- Rinse equipment in deionized water.
- Allow equipment to air dry.

The decontamination water was maintained in 5-gallon buckets during use, and transferred to 55-gallon drums for disposal. LEA field personnel were responsible for preventing cross-contamination between soil samples collected for laboratory analysis. Sample preparation tables were covered with clean, disposable plastic. Clean, disposable plastic was also laid on the ground beneath the sample preparation tables and the decontamination solutions to catch dropped soil and spilt decontamination solutions.

2.10 Soil Boring Location Identifiers

Monitoring wells, as well as piezometers, stream gauges, surface water and sediment sampling locations, and soil borings, have been provided with location identifiers using a systematic method to prevent duplication of location identifiers. The system of location identifiers provides a relatively easy means of finding the referenced locations on site maps. All parts of the P&W East Hartford facilities, including the Andrew Willgoos Gas Turbine Laboratory, the Colt Street

DRAFT

facility, and the Main Street facility, have been divided into twenty-nine study areas. Each of the study areas has been assigned two-letter identifiers based upon the common name for the area. These two-letter designations are presented in Table 2.

In addition, each type of sampling location has been assigned a two-letter designation to identify the major sample type for a given sampling location. The two-letter designations for the various types of sampling locations are also presented in Table 2. Because of the large areas involved, the study areas that encompass the Airport/Klondike Area include the North and South Airport Areas and the North and South Klondike Areas. All monitoring and sampling locations have been given a location identifier based on their location in the Airport/Klondike Area, the type of sampling or monitoring location, and finally a sequential numeric identifier based upon the specific type of location. All soil boring locations are presented on Drawings TM5-1 through TM5-4 which cover the entire Airport/Klondike Area.

2.11 Waste Management

All spent decontamination fluids generated during drilling activities for the investigation were placed in 55-gallon closed-top drums supplied by P&W for subsequent off-site disposal by P&W. The drums were labeled, the soil borings contributing to each were listed, and the information tracked to aid in waste characterization and disposal.

All soil cuttings generated during drilling activities were placed in 55-gallon open-top drums supplied by P&W for subsequent off-site disposal by P&W. The drums were labeled, the soil borings contributing to each were listed, and the information tracked to aid in waste characterization and disposal.

2.12 Health and Safety

LEA field personnel conducted field activities in accordance with the LEA Site Health and Safety Plan that was prepared for all of the investigation activities performed at the Site. In general, soil boring advancement was conducted in modified Level D personal protective equipment (PPE) consisting of safety glasses, surgical or nitrile gloves, steel-toed shoes, and hard hats. Drilling contractors employed as subcontractors operated in accordance with their specific health and safety plans.

DRAFT

3. RESULTS

A total of 725 soil borings have been installed in the Airport/Klondike Area. A total of 58 soil borings were installed in the North Airport Area; 243 soil borings were installed in the North Klondike Area; 165 soil borings were installed in the South Airport Area; and 259 soil borings were installed in the South Klondike Area. The locations of these soil borings are shown on Drawings TM5-1 through TM5-4.

Soil borings were generally completed to a depth of 16 feet below the ground surface, refusal, or the top of the clay unit, depending upon the purpose of the soil boring, the depth to the clay, and the general geologic material in the area. A depth of 16 feet was chosen because it exceeds the depth of 15 feet specified for the direct exposure criteria of the Connecticut Remediation Standard Regulation(RSR). Selected soil borings were completed to shallower depths where the soil borings were installed to provide confirmational samples for previous soil samples, or for other specific sample collection purposes. The general rationale for the location, total depths, analytical parameters, and sampling intervals for the specific soil borings is presented in the appropriate USTMs.

Refusal was not typically encountered in the Airport/Klondike Area. In the Linde Gas Area, refusal was encountered for borings installed through the concrete slab of the former chemical storage building. In this area it is presumed that refusal was due to the backfill material associated with the construction of the chemical storage building and not to natural conditions of the site.

The clay layer underlying the site provides an effective barrier to vertical contaminant migration, and as such, soil borings were not typically continued when the clay unit was encountered.

Table 1 summarizes the analytical parameters applicable to specific soil samples collected from soil borings at the Site. Specific analytical results and the rationale for soil boring locations and sample selection are discussed in the appropriate USTMs. The soil borings associated with specific environmental units is presented in Table 3.

Geologic boring logs for soil borings are presented in Attachment A. In general, geologic data derived from soil borings was used to supplement the geologic data derived from the monitoring wells. Monitoring wells were used as the major source of information for describing the surficial geology of the Site. Site-specific geology is discussed in Section 5 of the report.
